Edge detection

- Goal: Identify sudden changes (discontinuities) in an image
 - Intuitively, most semantic and shape information from the image can be encoded in the edges

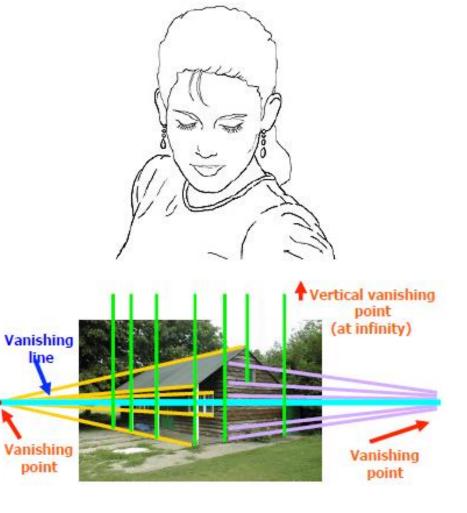

• Ideal: artist's line drawing

Why do we care about edges?

 Extract information, recognize objects

 Recover geometry and viewpoint

Source: J. Hayes

Origin of edges

• Edges are caused by a variety of factors:

Edge Models

Characterizing edges

An edge is a place of rapid change in the image intensity function

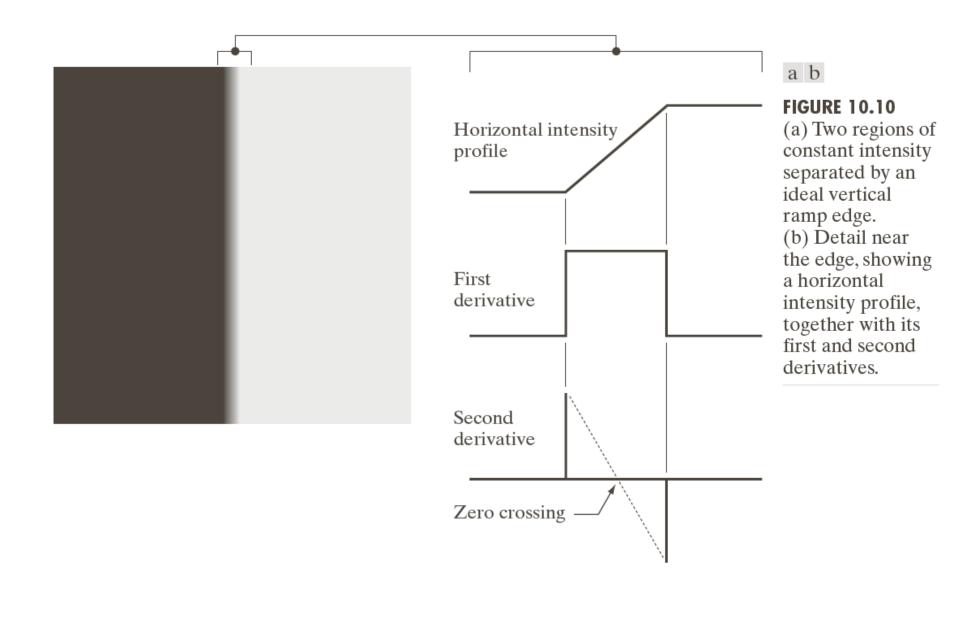

Background

First-order derivative

$$\frac{\partial f}{\partial x} = f'(x) = f(x+1) - f(x)$$

Second-order derivative

$$\frac{\partial^2 f}{\partial x^2} = f(x+1) + f(x-1) - 2f(x)$$

Characteristics of First and Second Order Derivatives

First-order derivatives generally produce thicker edges in image

Second-order derivatives have a stronger response to fine detail, such as thin lines, isolated points, and noise

Second-order derivatives produce a double-edge response at ramp and step transition in intensity

The sign of the second derivative can be used to determine whether a transition into an edge is from light to dark or dark to light

Image gradient

• The gradient of an image: $\nabla f = \left[\frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}\right]$

$$\nabla f = \begin{bmatrix} \frac{\partial f}{\partial x}, 0 \end{bmatrix}$$

$$\nabla f = \begin{bmatrix} \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y} \end{bmatrix}$$

$$\nabla f = \begin{bmatrix} 0, \frac{\partial f}{\partial y} \end{bmatrix}$$

The gradient points in the direction of most rapid increase in intensity

How does this direction relate to the direction of the edge?

The gradient direction is given by

$$\theta = \tan^{-1}\left(\frac{\partial f}{\partial y}/\frac{\partial f}{\partial x}\right)$$

The edge strength is given by the gradient magnitude

$$\|\nabla f\| = \sqrt{\left(\frac{\partial f}{\partial x}\right)^2 + \left(\frac{\partial f}{\partial y}\right)^2}$$

Gradient magnitude

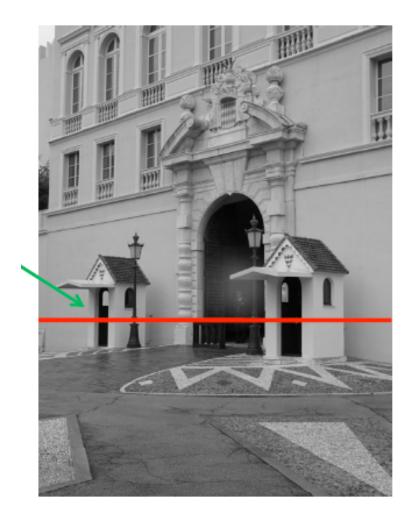

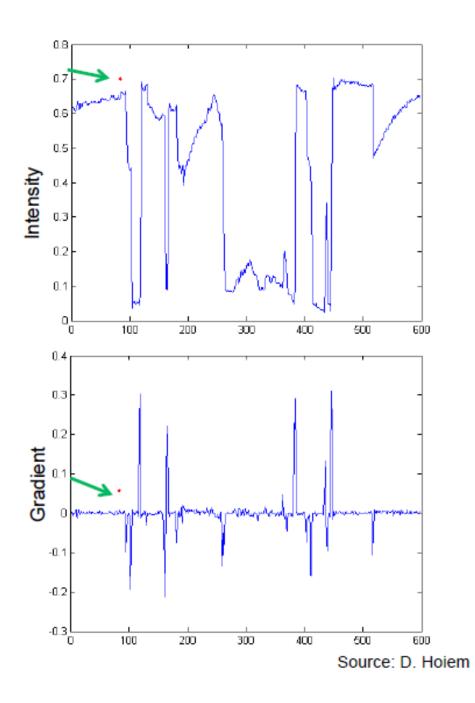

y-direction

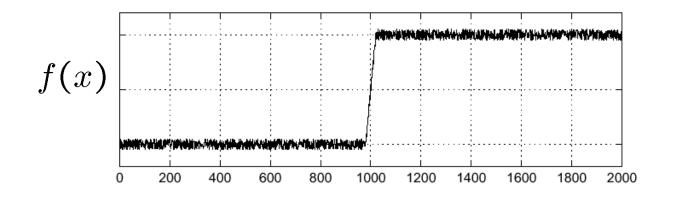

Intensity profile

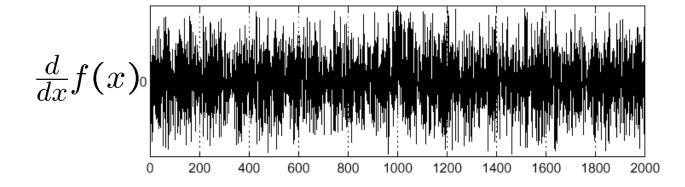

Effects of noise

- Consider a single row or column of the image
 - Plotting intensity as a function of position gives a signal

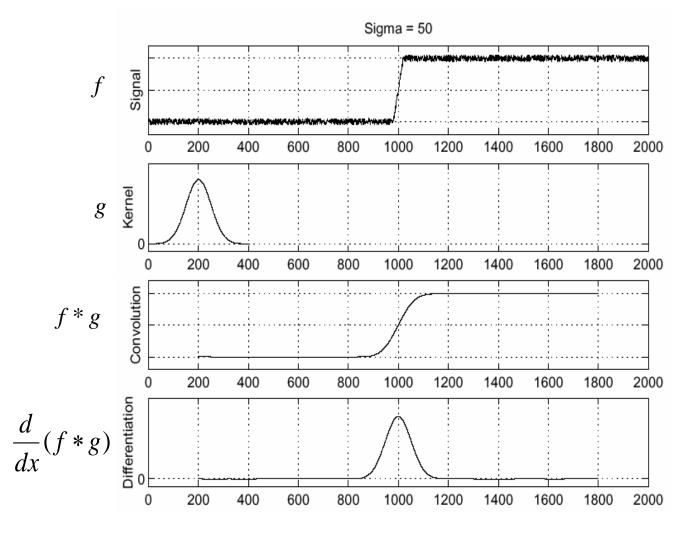

Where is the edge?

Effects of noise

- Finite difference filters respond strongly to noise
 - Image noise results in pixels that look very different from their neighbors
 - Generally, the larger the noise the stronger the response
- What is to be done?

Solution: smooth first

• To find edges, look for peaks in

$$\frac{d}{dx}(f*g)$$

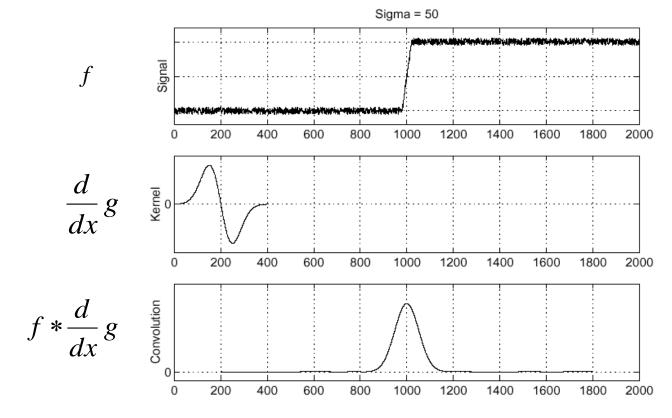

Source: S. Seitz

Derivative theorem of convolution

• This theorem gives us a very useful property:

$$\frac{d}{dx}(f * g) = f * \frac{d}{dx}g$$

• This saves us one operation:

Marr-Hildreth Algorithm

- 1. Filter the input image with a nxn Gaussian lowpass filter. N is the smallest odd integer greater than or equal to 6
- 2. Compute the Laplacian of the image resulting from step1
- 3. Find the zero crossing of the image from step 2

$$g(x,y) = \nabla^2 \left[G(x,y) \star f(x,y) \right]$$

Derivative of Gaussian filter

Detection of Isolated Points

• The Laplacian

$$\nabla^2 f(x, y) = \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2}$$

$$= f(x+1, y) + f(x-1, y) + f(x, y+1) + f(x, y-1)$$

$$-4f(x, y)$$

$$g(x,y) = \begin{cases} 1 & \text{if } |R(x,y)| \ge T \\ 0 & \text{otherwise} \end{cases} R = \sum_{k=1}^{9} w_k z_k$$

Implementation issues

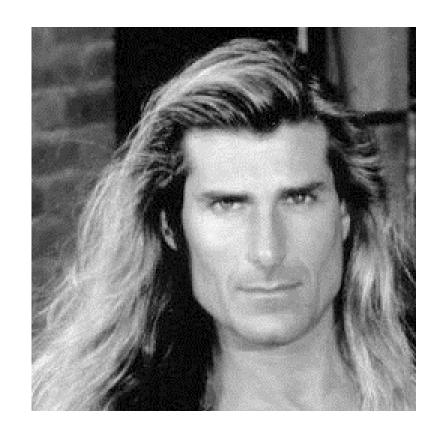

- The gradient magnitude is large along a thick "trail" or "ridge," so how do we identify the actual edge points?
- How do we link the edge points to form curves?

Canny edge detector

- Criteria for a good edge detector:
 - Good detection: the optimal detector should find all real edges, ignoring noise or other artifacts
 - Good localization
 - the edges detected must be as close as possible to the true edges
 - the detector must return one point only for each true edge point
- J. Canny, <u>A Computational Approach To Edge Detection</u>, IEEE Trans. Pattern Analysis and Machine Intelligence, 8:679-714, 1986.

Examples:

'Lena'

'Fabio'

The Canny Edge Detector: Algorithm

Let f(x, y) denote the input image and G(x, y) denote the Gaussian function:

$$G(x, y) = e^{-\frac{x^2 + y^2}{2\sigma^2}}$$

We form a smoothed image, $f_s(x, y)$ by convolving G and f:

$$f_s(x, y) = G(x, y) \star f(x, y)$$

The Canny Edge Detector: Algorithm

Compute the gradient magnitude and direction (angle):

$$M(x, y) = \sqrt{g_x^2 + g_y^2}$$

and

$$\alpha(x, y) = \arctan(g_y / g_x)$$

where
$$g_x = \partial f_s / \partial x$$
 and $g_y = \partial f_s / \partial y$

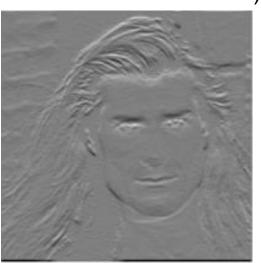

Compute Gradient Magnitude

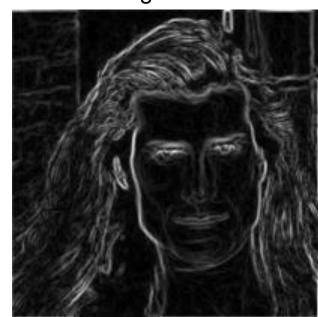

sqrt(X-Deriv.ofGaussian ^2 + Y-Deriv.ofGaussian ^2)

= gradient

Compute Gradient Orientation

theta = atan2(gy, gx)

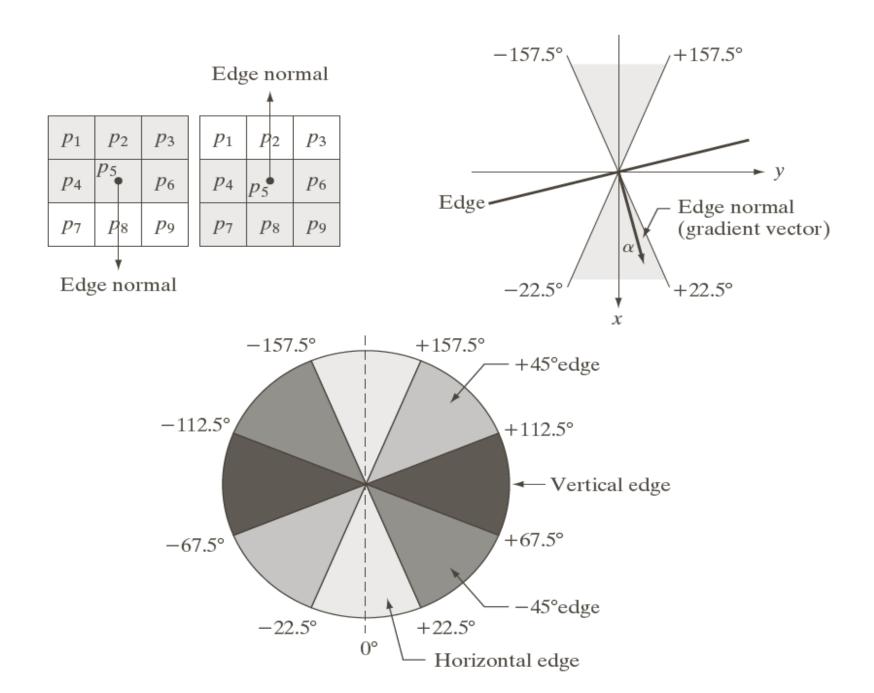

The Canny Edge Detector: Algorithm

The gradient M(x, y) typically contains wide ridge around local maxima. Next step is to thin those ridges.

Nonmaxima suppression:

Let d_1, d_2, d_3 , and d_4 denote the four basic edge directions for a 3×3 region: horizontal, -45°, vertical,+45°, respectively.

- 1. Find the direction d_k that is closest to $\alpha(x, y)$.
- 2. If the value of M(x, y) is less than at least one of its two neighbors along d_k , let $g_N(x, y) = 0$ (suppression); otherwise, let $g_N(x, y) = M(x, y)$

Before Non-max Suppression

Gradient magnitude

After non-max suppression

Gradient magnitude

The Canny Edge Detector: Algorithm

The final operation is to threshold $g_N(x, y)$ to reduce false edge points.

Hysteresis thresholding:

$$g_{NH}(x, y) = g_N(x, y) \ge T_H$$
$$g_{NL}(x, y) = g_N(x, y) \ge T_L$$

and

$$g_{NL}(x, y) = g_{NL}(x, y) - g_{NH}(x, y)$$

The Canny Edge Detector: Algorithm

Depending on the value of T_H , the edges in $g_{NH}(x, y)$ typically have gaps. Longer edges are formed using the following procedure:

- (a). Locate the next unvisited edge pixel, p, in $g_{NH}(x, y)$.
- (b). Mark as valid edge pixel all the weak pixels in $g_{NL}(x, y)$ that are connected to p using 8-connectivity.
- (c). If all nonzero pixel in $g_{NH}(x, y)$ have been visited go to step (d), esle return to (a).
- (d). Set to zero all pixels in $g_{NL}(x, y)$ that were not marked as valid edge pixels.

Final Canny Edges
